Energy Outlook 2015: Focus on the Electricity Supply Mix

for
Natural Gas Power Generation US
May 18, 2015 | Philadelphia, Pennsylvania

by
Howard Gruenspecht, Deputy Administrator
U.S. Energy Information Administration

• Statistical and analytical agency within the U.S. Department of Energy

• Produces monthly short-term and annual long-term projections

• Produces special analyses of emerging issues and regulatory changes

• EIA’s analyses and projections are independent, by law, and should not be seen as representing the views of the Department of Energy, the Administration, or any other organization.
Short-term

U.S. electricity generation by energy source
gigawatthours per day

Source: EIA, Short-Term Energy Outlook, April 2015
In EIA’s forecast, coal’s share of summer generation falls to historic low while natural gas and renewables match or exceed record highs.

average daily power generation, by fuel source, April through October
billion kilowatt hours per day

Source: Electric Power Monthly, EIA Short-Term Energy Outlook April 2015
Coal plant retirements have had minimal impact on gas use for generation to date

- Recent and near-term coal retirements have operated at below-average capacity factors
- Average capacity factor for coal plants is 58%
- Low natural gas prices have been the main driver of coal displacement

Note: Estimates for 2015 and 2016 subject to change based on EIA-860 survey responses
Source: EIA, Annual Energy Outlook 2015; Electric Power Annual 2013
EIA forecast for Henry Hub prices is slightly above the Nymex strip through 2016; however, confidence intervals based on options values suggest a wide band of uncertainty in price projections.
Industrial and power sectors drive natural gas consumption growth in the forecast

May 12, 2015
Long-term
AEO2015 underpinnings

• Reference case: assumes current laws and regulations
  - Reinstatement of the Clean Air Interstate Rule (CAIR) after the court's announcement of intent to vacate the Cross-State Air Pollution Rule (CSAPR)
  - Includes representation of Mercury and Air Toxics Standards (MATS), with effective implementation date assumed to be 2016 rather than 2015
  - Includes state renewable portfolio standards
  - Represents California’s cap-and-trade program and the Northeast’s RGGI program
  - DOES NOT include EPA’s proposed Clean Power
Key results from **AEO2015**

- In most AEO2015 cases, U.S. net energy imports, including all fuels, decline and ultimately end by 2030 for the first time since the 1950s.

- U.S. energy consumption grows at a modest rate over the projection with reductions in energy intensity resulting from improved technologies and trends driven by existing laws and regulations.

- Renewables provide an increased share of electricity generation, reflecting rising long-term natural gas prices and the high capital costs of new coal and nuclear generation capacity.

- Improved efficiency of energy consumption in end-use sectors and a shift away from more carbon-intensive fuels help to stabilize U.S. energy-related carbon dioxide emissions, which remain below the 2005 level through 2040.

- Hydrocarbon production varies significantly across regions and cases; shifts in flows between regions require infrastructure adjustments.

- The AEO2015 cases generally reflect current policies, including final regulations and the sunset of tax credits under current law; they do not consider EPA’s proposed Clean Power Plan for existing fossil-fired electric generating units or the effects of relaxing current limits on crude oil exports.
Reductions in energy intensity largely offset impact of GDP growth, leading to slow projected growth in energy use.

Source: EIA, Annual Energy Outlook 2015 Reference case
Over time the electricity mix gradually shifts to lower-carbon options, led by growth in renewables and gas-fired generation.
Future domestic natural gas prices depend on both domestic resource availability & technology and world energy prices.

Average Henry Hub spot prices for natural gas, 2013 dollars per million Btu.

With lower natural gas prices in the High Oil and Gas Resource case, coal is displaced as the leading generation source before 2020.

Source: EIA, Annual Energy Outlook 2015
In 2013, the average delivered price of coal to electricity generators varied widely across U.S. regions – transport costs are a key reason.

The proposed Clean Power Plan for existing units under 111(d) is not a simple emission rate standard for existing units; provisions affecting the denominator in compliance calculations play a key role.

Key takeaways regarding the outlook for natural gas storage levels

- **Natural gas storage is substantially higher than at this time last year:** End-of-March 2015 inventories total an estimated 1,471 Billion cubic feet (Bcf), compared to 857 Bcf in 2014 following large withdrawals due to the exceptionally cold winter of 2013-2014

- **Strong production:** EIA forecasts average production over the upcoming injection season to be 3.5 Bcf/d greater than production the same time last year

- **Near-record natural gas consumption for electric generation expected due to relatively low natural gas prices and warmer summer weather:** EIA forecasts that the average Henry Hub price over the injection season is $3.06/MMBtu, much lower than the average of $4.21/MMBtu last year. NOAA’s forecast of cooling degree days for the April – October 2015 injection season is 6.9% above the comparable 2014 period, implying more air conditioning demand

- **Relatively strong injections in the coming months:** EIA expects an overall injection of 2,310 Bcf between April and October, with stocks at the end of October forecast to reach 3,781 Bcf, 194 Bcf higher than 2014
Forecast for natural gas consumed in the electric power sector is about 11% greater than last summer’s levels, but 4% below 2012’s record high levels.
