Preface

The Energy Information Administration (EIA) reports detailed historical data on renewable energy consumption and electricity annually in its report, the *Renewable Energy Annual*. This report, *Renewable Energy Trends in Consumption and Electricity*, 2006, provides an overview and tables with historical data spanning as far back as 1989 through 2006, including revisions. These tables correspond to similar tables to be presented in chapter 1 of the *Renewable Energy Annual 2006* and are numbered accordingly.

Also following the highlights section which provides an overview, the report contains four "Issue in Focus" sections designed to provide an in-depth look at some of the major issues affecting renewable energy in the near term. The topics are:

- Wind Energy Developments
- Central Station Solar Thermal Electricity: Concentrating Solar Power Comes of Age
- Biodiesel in the Energy Supply
- Wave and Tidal Energy

The renewable energy resources in the report include: biomass (wood, wood waste, biogenic municipal solid waste (MSW), landfill gas, ethanol, biodiesel and other biomass); geothermal; wind; solar (solar thermal and photovoltaic); and conventional hydropower. Hydroelectric pumped storage is excluded, because it is usually based on non-renewable energy sources.

Definitions for terms used in this report can be found in EIA's Energy Glossary: http://www.eia.doe.gov/glossary/index.html. General information about all the EIA surveys with data related to renewable energy and referenced in this report can be found here: http://www.eia.doe.gov/oss/forms.html.

Highlights 2006

Consumption

Total renewable energy consumption increased by 478 trillion Btu or 7 percent between 2005 and 2006 to 6,922 trillion Btu (Table 1.1). At the same time total US energy consumption decreased 1 percent largely due to decreases across the board in fossil fuel energy consumption. The combination of these trends resulted in moving renewable energy's share of total US energy to nearly 7 percent, up from over 6 percent in 2005 (Figure 1.1).

Figure 1.1 The Role of Renewable Energy Consumption in the Nation's Energy Supply, 2006

Source: Table 1.1 of this report.

During 2006 renewable energy consumption reached its highest level since 1997, which was a record year for hydropower due to water availability (Table 1.5a and Table 1.5b). Hydropower is the second largest source of renewable energy consumption.

Biomass and conventional hydroelectric power had the largest volumetric increases at 220 and 166 trillion Btu respectively, while wind energy consumption had the fastest annual rate of growth at almost 50 percent.

The electric power sector continued to be the largest consumer of renewable energy in 2006 (55 percent of total), primarily due to the very large contribution of conventional hydroelectric power (Table 1.2). The industrial sector was second (29 percent of the total), due to that sector's major consumption of wood and derived fuels. Geothermal and conventional hydropower played only minor roles in the industrial sector. The residential sector also consumed wood for space heating and solar energy for water heating and electricity. The commercial sector accounted for just 2 percent of total renewable energy consumption. The transportation sector was the fastest growing sector, consuming 40 percent more renewable fuel between 2005 and 2006. This is mainly due to increased ethanol consumption, by far the larger component of biofuels during those years.

Renewable energy used to produce electricity contributed 4.229 quadrillion Btu or 61 percent of total renewable energy consumption in 2006 (Table 1.2 and Table 1.3). Ninety percent of this energy was consumed in the electric power sector, which includes traditional electric utilities and independent power producers whose primary purpose is to sell electricity, or electricity and heat, to the public. Almost all of the remainder is used by the industrial sector. Nonhydro renewable electricity energy consumption expanded slowly from 1,278 to 1,360 trillion Btu between 2002 and 2006. Increases in wind consumption were partially offset by decreases in biomass.

Nonelectric uses of renewable energy made up the balance (2,693 trillion Btu or 39 percent) of renewable energy consumption (Table 1.2 and Table 1.4). Nonelectric uses include applications such as wood for space heating, noncentral station solar, process heat from biomass for manufacturers, geothermal heat pumps and direct use of geothermal, biofuels for transportation and losses and coproducts from the production of biofuels. Over the last five years the share of renewable energy consumed for nonelectric use expanded from 33 to 39 percent (Figure 1.2).

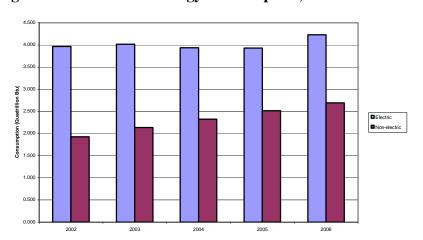

Figure 1.2 Renewable Energy Consumption, 2002-2006

Source: Table 1.3 and Table 1.4 of this report.

A major portion (over 65 percent) of the 745 trillion Btu increase in nonelectric biomass energy consumption from 2002 to 2006 was in biofuels. Table 1.6 (included for the first time in this report) presents an overview of biofuels, showing that a considerable amount of biomass energy is lost or goes to coproducts during production of ethanol. Ethanol production increased about 25 percent from 3.9 billion gallons in 2005 to 4.9 billion gallons in 2006. A number of factors contributed to this growth:

- Continued replacement of methyl tertiary butyl ether (MTBE) by ethanol as a gasoline additive.
- Strong world oil demand and higher crude oil prices, which have raised the price of gasoline and thus the demand for, and price of, ethanol as a substitute.
- Tax laws that provide incentives, such as the 51 cent per gallon Federal tax credit available to blenders for each gallon of ethanol blended into gasoline.
- The Energy Policy Act of 2005, which mandated annual renewable fuel use in gasoline at 5.4 billion gallons by 2008.

At 2006 production levels, ethanol accounted for nearly 4 percent of U.S. finished motor gasoline production.²

Ethanol consumption, when compared to production, increased at an even faster rate, 35 percent.³ The difference between production and consumption was largely made up of increased imports (principally from Brazil) and stock withdrawals. So total consumption for 2006 was 462 trillion Btu, up from just 175 trillion Btu in 2002 (Figure 1.3).

[&]quot;Monthly Oxygenate Report."

² Energy Information Administration, *Petroleum Supply Monthly*, February 2007 (Washington, DC, February 2007) Table 2.

³ Ethanol consumption is calculated as the sum of production, net imports, and stock changes.

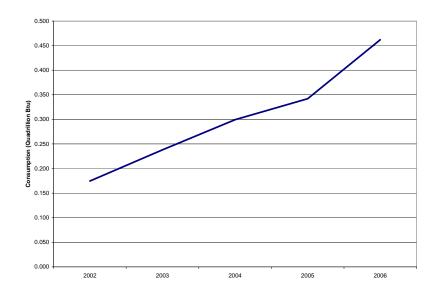

Figure 1.3 Ethanol Consumption, 2002-2006

Source: Table 1.2 of this report.

Biodiesel production also was in a period of growth and more than doubled between 2005 and 2006. A later section of this report on renewable issues presents general information to familiarize readers with the biodiesel industry.

In December 2007 the Energy Independence and Security Act (EISA) of 2007 was signed into law. ⁴ This boosted the renewable fuel standard to 9 billion gallons of renewable fuels by 2008 and 36 billion gallons in 2022. Assuming the targets are achieved, biofuels consumption (ethanol and biodiesel) will increase substantially from current levels.

Waste energy consumption stood at 407 trillion Btu in 2006 and was little changed from the previous few years. More than half of the waste energy was consumed by independent power producers (Table 1.7). MSW biogenic provided the most energy (42 percent) followed by landfill gas (37 percent).

Industrial biomass energy consumption increased about 6 percent between 2005 and 2006 (Table 1.2). The paper and allied products industries dominated biomass consumption in the industrial sector with 64 percent of the total (Table 1.8). Most of this was useful thermal output and a much smaller share was used to produce electricity. Biorefineries, which produce biodiesel and ethanol, and the lumber industry had the next largest shares with 15 and 13 percent of the total, respectively. In addition, fifty-two power plants in 23 states with total generating capacity of 6,317 megawatts reported having generators with biomass/coal cofiring capacity that totaled 3,569 megawatts (Table 1.9).

⁴ See EISA 2007 Title II here: http://thomas.loc.gov/cgi-bin/bdquery/z?d110:h6:

Electricity

Renewable energy provided almost 386 billion kilowatt hours of electricity generated in 2006 of a U.S. total of 4,065 billion kilowatthours. ⁵ While total U.S. electricity generation increased by 0.2 percent in 2006, conventional hydroelectric generation grew 7 percent and wind generation increased by nearly 50 percent, though from a much smaller base (Table 1.11 and Figure 1.4).

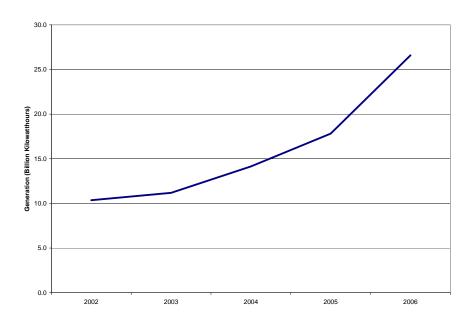

Figure 1.4 Wind Electricity Net Generation, 2002-2006

Source: Table 1.11 of this report.

Most of the electricity produced using renewable energy during 2006 was in the electric power sector, which accounted for 91 percent of the market; the industrial sector accounted for just 8 percent. In the same year, results were mixed for nonrenewable electricity. Nuclear- and coal-fired electricity generation stayed fairly steady, while electricity from petroleum plunged and natural gas rose 7 percent.

As a result of expanded government-sponsored renewable energy programs, total renewable electric capacity stood at 101,934 megawatts by the end of 2006, up from 98,746 megawatts in 2005 (Table 1.12). With an increase of 2,622 megawatts between 2005 and 2006 wind energy accounted for the largest increase in renewable capacity and the second largest increase in capacity nationwide. Natural gas capacity was first nationwide with an increase of over 5,000 megawatts. A later section of this report discusses wind electricity developments in detail.

⁵ Energy Information Administration, *Monthly Energy Review December 2007* (Washington, DC, December 2007), Table 7.2a

⁶ Energy Information Administration, *Electric Power Annual 2006* (Washington, DC, October 2007), Table 2.1.

Table 1.13 shows that conventional hydroelectric generation was concentrated in the Pacific Contiguous Census Division where it accounts for a major portion of electricity supplied to that market (Figure 1.6). Electricity from geothermal and solar/ photovoltaic (PV) energy was found mainly in the Pacific Contiguous and Mountain Divisions, while electricity from the remaining renewable energy sources tended to be scattered geographically. Nearly 98 percent of industrial biomass generation was provided by wood and wood derived fuels (principally, black liquor, wood/wood waste liquids and solids) mainly in the southern Census Divisions of the U.S. (Table 1.14).

State Electricity

Renewable electricity generation increased by 28 billion kilowatthours between 2005 and 2006. The largest increases were for conventional hydroelectric power in Washington, California, Oregon, Idaho and New York and for wind in California, Iowa, Oklahoma, and Texas (Table 1.17 and Table 1.20).

Renewable electric capacity increased by 3,189 megawatts between 2005 and 2006. Eighty-two percent of this increase was wind capacity. Texas, Washington, and California led that growth (Table 1.23 and Table 1.26). Most of the remainder of the capacity increase was for landfill gas/MSW biogenic (111 megawatts), wood and derived fuels (179 megawatts), and conventional hydroelectric (281 megawatts).

In 2006 renewable electricity generation captured 9.5 percent of the U.S. electricity market, while nonhydro renewable electricity took just 2.4 percent (Table 1.27). Some States had little or no renewable generation, while others had shares as high as 89 percent for Idaho, 78 percent for Washington, and 75 percent for Oregon. Maine had the largest share of nonhydro renewable electricity generation at 24 percent. In terms of volume, California had the most nonhydro renewable generation with 24 billion kilowatthours due to its diverse supply of renewable energy sources, which includes the majority of the nation's geothermal and solar power.

Although there is considerable variation in objectives and standards for enforcement, many States continue to expand their efforts to incorporate more renewable energy in their electric supply. By the end of 2007 32 states had enacted renewable portfolio standards (RPS) or state renewable mandates (Table 1.28 and Figure 1.5).

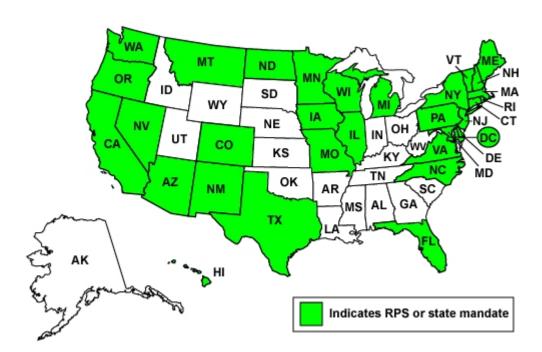

Figure 1.5 Renewable Portfolio Standards and State Mandates by State, 2007

Note: In Florida, Michigan and Missouri the RPS is not statewide. In some states, including Illinois, Michigan, Missouri, North Dakota, Virginia and Vermont, the renewable portfolio standard (RPS) is voluntary. Source: North Carolina Solar Center, Database of State Incentives for Renewable Energy (DSIRE) website: http://www.dsireusa.org (January 8, 2008).

These include the following states that were new on the list in 2007:

Michigan. Early in 2007, the Lansing Board of Power and Light (LBPL) established a series of voluntary goals for meeting its customers' electricity demand with renewable energy. The goal for 2016 is 7 percent of retail sales.

Missouri. In mid-2007, Missouri created a renewable energy and energy-efficiency objective for its investor owned utilities. Each utility must make a "good-faith effort" to generate or procure electricity generated by renewable energy equal to 11 percent of its retail electric sales by 2020. Credit towards the objective also may be achieved through energy efficiency that includes utility and consumer efforts to reduce consumption of electricity.

New Hampshire. In mid-2007, New Hampshire enacted a renewable portfolio standard that requires electricity providers to acquire renewable energy certificates (RECs). equivalent to 23.8 percent of retail electricity sold to end-use customers by 2025. Class I and II eligible new renewable sources (in operation after January 1, 2006) will provide 16.3 percent of retail electricity sold, while Class III and IV eligible existing renewable sources will provide 7.5 percent.⁷

⁷ For a detailed explanation of eligible energy sources, see the New Hampshire Code of Administrative Rules, Chapter Puc 2500 Electric Renewable Portfolio Standard, here: http://www.puc.state.nh.us/Regulatory/Rules/Puc2500%20Interim%20Rules%20-%20January%2010%202008.pdf

North Carolina. In mid-2007, North Carolina enacted a Renewable Energy and Energy Efficiency Portfolio Standard. Basically, this requires investor owned utilities to supply electricity equivalent to 12.5 percent of their 2020 sales using renewable energy or eligible alternatives by 2021. Up to 25 percent of the requirement can be met through energy efficiency technologies, including combined heat and power systems powered by nonrenewable energy sources. Municipal utilities and electric cooperatives must meet a target of 10 percent of their sales coming from renewables by 2018 but using slightly different rules.

North Dakota. Early in 2007, North Dakota enacted legislation establishing a goal that 10 percent of all retail electricity sold in the state is to be obtained from renewable energy and recycled energy by 2015. The goal is voluntary.

Oregon. At about the same time in 2007 that Oregon's governor signed the Western Climate Initiative, the state enacted its renewable portfolio standard. In summary the standard is stepped in over the years from 2011 to 2025 and it varies by the size of the utility's load. In practice this means that the three large utilities (each with three percent or more of Oregon's total retail sales) will meet a target of 5 percent of electricity sold from renewable energy by 2011 and 25 percent by 2025, while smaller utilities will have lower targets. 9

Virginia. As part of its legislation to reregulate the state's electricity industry, Virginia enacted a voluntary renewable energy portfolio goal. The goal for investor owned utilities is to have 12 percent of base load sales in 2007 in Virginia (less the average annual percentage of power supplied from nuclear generators between 2004 and 2006) to come from renewable energy sources by 2022.

A number of other states including Arizona, Colorado, Delaware, Maryland, Minnesota, Montana, New Mexico, and Pennsylvania expanded the provisions of their renewable portfolio standards in 2007.

⁸ The agreement establishing the Western Climate Initiative was signed in February 2007. Targets to lower greenhouse gases to 15 percent below 2005 levels by 2020 were announced in August. Oregon enacted the renewable portfolio standard that would support that mission in June 2007.

⁹ For details such as the list of eligible sources, the matrix of RPS targets, implementation plans, and possible exemptions and modifications to the targets, etc., see the Oregon Department of Energy website, here: http://www.oregon.gov/ENERGY/RENEW/docs/Oregon_RPS_Summary_Oct2007.pdf.

Data Revisions

Estimates of residential wood consumption were revised upward for 2005 and 2006 to reflect a higher number of households reported as having wood burning units in the preliminary data from the EIA Residential Energy Consumption Survey 2005. Renewable electricity data for 2006 is now final.

Also a new source of data was found for feedstocks consumed to produce inedible methyl esters (biodiesel). This was used to estimate biodiesel production and apparent consumption starting in 2006 after the U.S. Department of Agriculture's Commodity Credit Corporation ended its biodiesel program.

Issue in Focus: Wind Energy Developments

Introduction

Although wind power has developed rapidly in the United States since 2000, it still did not provide a substantial amount of electricity until 2006, when wind energy produced 27 billion kWh. This represents half the amount provided by biomass, but nearly 83 percent more than the amount provided by geothermal. The fact that wind provided 7 percent of renewable-based electricity during 2006 -- and 28 percent of non-hydro renewable generation--is due to the large amount of new wind capacity which has come on line since the turn of the century. In particular, total installed wind capacity increased from 4,417 MW in 2002 to 11,329 MW in 2006, with 2,600 MW of the increase coming during 2006 alone (Table 1.H1).

The top five states for wind capacity in 2006 were Texas, California, Iowa, Minnesota and Washington. In 2006, Texas overtook California, which had been the leading wind capacity state since the inception of the modern wind power industry in the 1980's. The biggest single project in 2006 was the expansion of Buffalo Mountain Energy Center (also known as the Horse Hollow Wind Energy Center) in Texas. In 2006 it was considered to be the largest wind plant in the world at 736 MW.

Not only has total wind capacity expanded rapidly, but since 2002 wind projects have also been built in 9 additional states: Alaska, Idaho, Illinois, Montana, New Jersey, New Mexico, North Dakota, Ohio and Oklahoma. ¹² This makes a total of 28 states with wind capacity of 1 megawatt or more. Oklahoma now has almost 600 MW of wind, and New Mexico has 500 MW.

The major factors driving this growth include the Federal Production Tax Credit (PTC) and state policies to encourage renewable energy. These topics are discussed in the materials that follow, in the context of the underlying issues of global warming, the cost of natural gas, and limits on the electricity transmission infrastructure.

Federal Production Tax Credit

The Federal production tax credit, originally enacted as part of the Energy Policy Act of 1992 (EPACT 92), was set at 1.5 cents per kilowatthour for all electricity generated in the first ten years of the life of the project. According to EPACT 92, the credit is to be adjusted for inflation, and in 2008 it was set at two cents per kilowatthour for all wind projects in operation before the current expiration date (December 31, 2008) for the first

¹¹ See http://www.fplenergy.com/news/contents/101906.shtml .

¹² Some states, such as Alaska, may have had some small wind plants in operation before 2006 that were not included in EIA estimates, because power plants must be 1 megawatt or more in capacity to be included in EIA reported data.

Source: Energy Information Administration, Form EIA-860, "Annual Electric Generator Report."

ten years of the project's life. ^{13,14} This tax credit in some regions/localities may make wind power competitive with electricity generated by more conventional sources. ^{15,16} In the past there has been uncertainty over the availability of the PTC. Twice recently (at the end of 2001 and again in October 2004) the PTC expired, and there was a gap between the expiration and the time it was reinstated. During each of these gaps, little additional wind capacity came on line. Currently, the wind industry is in a period of relative stability, because the credit was renewed without a break in 2005 and again in 2006 and will not expire until the end of 2008. The flow of new projects and expansion has been steady compared to earlier years, when there were bursts of activity followed by periods of little activity. The debate on continuing the PTC is ongoing. ¹⁷

Texas

In 2006 Texas was first among states in the Nation in total electrical capacity, net generation and total retail sales. ¹⁸ Forty- nine percent of its generation in 2006 was from natural gas, and the average delivered price of natural gas to the electric power industry in Texas has almost doubled since 2002. Although Texas is still the leading state in U.S. crude oil production, output is off nearly 60 percent since 1981. Therefore, Texas is turning its attention to developing new energy sources as its oil production continues to decline. ¹⁹

In 1999, the Public Utility Commission of Texas (PUCT) adopted rules for the state's Renewable Energy Mandate, calling for 2,000 MW of new renewable capacity to be installed in Texas by 2009 and for a system of renewable energy credits to be established.²⁰ The ten-year goal was achieved within just six years, mainly with additions of wind capacity. After that success, the state legislature passed Senate Bill 20 in 2005, which increased the state's goal to 5,880 MW by 2015, of which 500 MW must come from non-wind resources. In 2006 alone, Texas added 460 MW at new wind plants

¹³ Technologies that qualify are wind, solar, geothermal and "closed-loop" dedicated bioenergy facilities. Other technologies such as "open-loop" biomass, incremental hydropower, small irrigation systems, landfill gas, and municipal solid waste receive a lesser credit.

¹⁴ The December 2008 expiration is the latest in a series of expiration dates, which started with the original sunset date of June 30, 1999.

¹⁵ Tax-excempt entities clearly cannot take advantage of this provision. However, they are eligible for another credit, known as the Renewable Energy Production Incentive (REPI).

and 523 MW to an existing plant. Also, Texas reported the largest number of green pricing customers in any single state for 2006 - 100,950.

Some of the best wind resources and sites for development in the state are distant from areas of demand, so Texas has had to resolve transmission congestion issues that forced periodic curtailment in some of the early wind projects and could hamper deliveries of future electricity supplies to market. For example, state Senate Bill 20 required that competitive renewable energy zones (CREZ) be designated in the best areas in the state and that electric transmission infrastructure be constructed to move renewable energy from those zones to markets where people use the electricity. This mechanism is designed to get transmission out to prime wind energy areas in advance of wind development, rather than trying to catch up to development as happened in Texas during the first part of this decade. In early October 2007, the PUCT issued an Interim Final Order that designated five CREZ in West Texas and the Texas Panhandle and authorized development of the necessary transmission lines. The final order is expected in early 2008. Since 85 percent of Texas transmission does not cross state lines, it is not subject to Federal Regulatory Energy Commission (FERC) regulation, so the state can act on its own in those areas and thus potentially expedite the process.

Washington

Washington was second in wind capacity additions for 2006, with 428 MW coming on line. This included the Wild Horse Wind Facility (229 MW) by Puget Sound Energy, a regulated electric utility. As part of its least cost resource plan, Puget Sound Energy considered the anticipated cost of various resources, as well as the cost of carbon dioxide emissions in the future and the risk of fossil fuel price spikes. As early as September 2003, Washington's governor joined the governors of California and Oregon to announce the West Coast Governors' Global Warming Initiative. By 2004, the governors had issued detailed recommendations on how this might be accomplished. In August 2007, members of the Western Climate Initiative, including Washington state, announced a regional, economy-wide greenhouse gas emissions target of 15 percent below 2005 levels by 2020. Evels

In response to these and other concerns, in November 2006 Washington voters passed ballot Initiative 937, which included a renewable portfolio standard. ²⁶ But Washington is

no newcomer to renewable energy. In 2006, over three-fourths of its generation was sourced to conventional hydroelectric power and 2.3 percent to other renewable energy.²⁷ The new standard calls for all electric utilities that serve more than 25,000 customers to obtain 15 percent of their electricity from new renewable energy resources by 2020 and to undertake all cost-effective energy conservation. Most conventional hydroelectric generation is excluded.

Eligible renewable electricity includes electricity produced from:

- eligible water;
- wind:
- solar energy;
- geothermal energy;
- landfill gas;
- wave, ocean, or tidal power;
- gas from sewage treatment facilities;
- eligible biodiesel fuel (must meet specified standards); and
- eligible biomass energy.

Electricity from biomass must be derived from animal waste or solid organic fuels from wood, forest, field residues, or dedicated energy crops. Specifically excluded from the definition are wood pieces that have been treated with chemical preservatives such as creosote (e.g., utility poles), pentachlorophenol, or copper-chrome arsenic; black liquor byproduct from paper production; wood from old growth forests; and municipal solid waste (MSW).

Electricity from renewable resources other than fresh water is eligible for compliance if the generation facility began operation after March 31, 1999. The facility must be located in the Pacific Northwest, or the electricity from the facility must be delivered into Washington State on a real-time basis. Hydroelectric generation projects are eligible if incremental electricity produced as a result of efficiency improvements completed after March 31, 1999, are made to:

- hydroelectric projects owned by a utility subject to the renewable portfolio standard and located in the Pacific Northwest; or to
- hydroelectric generation in irrigation pipes and canals located in the Pacific Northwest, where the additional generation in either case does not result in new water diversions or impoundments.

In the future, new wind projects proposed for Washington State may further contribute to meeting its commitments to increase renewable electricity production. For example, Puget Sound Energy's 2007 Integrated Resource Plan includes plans for more wind.²⁸

²⁷ Energy Information Administration, State Electricity Profiles 2006 Edition, see website here: http://www.eia.doe.gov/cneaf/electricity/st_profiles/washington.html.

²⁸ Puget Sound Energy press release for May 31, 2007, "Conservation, wind power, natural gas drive 20-year resource plan for Puget Sound Energy," here http://www.pse.com/insidePSE/news2007IRP.aspx.

However, Washington's electric power industry is operating in a regional context. For instance, the other project for 2006, the Rock River I LLC wind facility (a 199 MW plant also known by the name Big Horn) was developed to provide electricity to a joint power authority in California that includes the Modesto Irrigation District, Silicon Valley Power (Santa Clara), and the City of Redding.

California

California has long been a leader in renewable energy in the U.S., beginning after the world oil crisis of the late 1970's. As late as 2000, California had nearly two-thirds of U.S. wind capacity. Since then, however, wind energy growth in California has been slower than in other states, despite adding 203 MW in 2006 and having public policies in place to support wind energy development (Figure 1.5). Thus, Texas was able to surpass California in 2006 as the state with the most wind capacity. To understand why this has occurred, it is instructive to examine California's recent efforts to promote renewable energy.

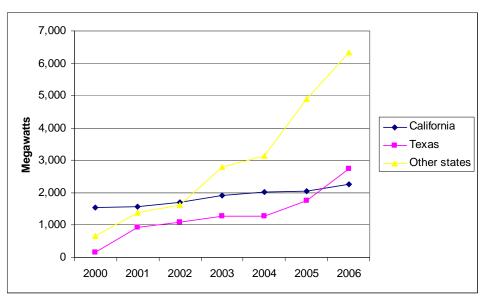

Figure 1.7 Wind Capacity by State, 2000-2006

Sources: Energy Information Administration, Form EIA 860A, "Electric Generator Report – Utility," Form EIA-860B, "Annual Electric Generator Report – Nonuitlity," and Form EIA-860, "Annual Electric Generator Report."

In 2002, California Senate Bill 1078 established a renewable portfolio standard with the goal of increasing to 20 percent (by 2017) the percentage of the state's electricity from renewable energy that is sold to retail customers. The 2003 Energy Action Plan adopted by the California Energy Commission (CEC) and the California Public Utilities Commission (CPUC) accelerated that target date to 2010.

Eligible renewable resources generally include:

- Biodiesel
- Biomass
- Conduit hydroelectric
- Fuel cells using renewable fuels
- Digester gas
- Geothermal
- Landfill gas
- Municipal solid waste
- Ocean wave, ocean thermal, and tidal current
- Photovoltaic
- Small Hydroelectric (30 Megawatt)
- Solar thermal electric
- Wind.²⁹

Eligibility of renewable facilities varies by type of technology and date that the facility became operational.³⁰ Most facilities in operation after September 1996 are eligible as are certain ones before then, but there are exceptions. Most, but not all, MSW combustion is excluded.³¹

Out-of-state generation that is delivered into California also counts towards meeting the RPS. The Western Region Electricity Generation Information System (WREGIS) will be used to ensure that renewable energy output is counted only once for the purpose of meeting the RPS in California or any other state, and for verifying retail product claims.³²

In addition, California has commitments to reduce global warming. In September 2006, the governor signed Assembly Bill 32, the Global Warming Solution Act. This Act caps California's greenhouse gas emissions at 1990 levels in 2020. California is also a party to the Western Climate Initiative. Development of renewable energy is expected to be part of the solution.

However in the CEC's 2007 Integrated Energy Policy Report of November 2007, the CEC reports that California is not on track to meet its RPS goals:

"Renewable generation in 2006, for all entities serving retail load, was at 10.9 percent, just below the percentage in 2002 before the RPS began. While delivered

²⁹ Specific details may be found in California Energy Commission, *Renewable Portfolio Standard Eligibility – Guidebook Second Edition* (March 2007). See website here:

http://www.energy.ca.gov/2007publications/CEC-300-2007-006/CEC-300-2007-006-CMF.PDF ³⁰ Specific details may be found in California Energy Commission, *Renewable Portfolio Standard Eligibility – Guidebook Second Edition* (March 2007). See website here: http://www.energy.ca.gov/2007publications/CEC-300-2007-006/CEC-300-2007-006-CMF.PDF

³¹ For example, MSW combustion located in Stanislaus county and operational prior to September 26, 1996 is allowed.

³² WREGIS is an independent, renewable energy tracking system for the region covered by the Western Electricity Coordinating Council (WECC). WREGIS tracks renewable energy generation from units that register in the system using verifiable data and creates renewable energy certificates (RECs) for this generation.

renewable energy has grown, load has also continued to grow, and delivered energy has essentially kept even, rather than increasing in percentage terms as required."³³

As for the near term,, the report states:

"Although the percentage of renewable deliveries has been flat, there is a large amount of contracted renewable energy that is likely to come on line in the next 2 to 5 years as new transmission to the Tehachapi and Imperial Valley becomes available."

Thus, it is likely California will miss meeting the 2010 target by at least several years. By inference, the slowdown in recent renewable energy capacity additions, especially wind, appears to be due in sizable measure to lack of sufficient electricity transmission capability.

Conclusion

Clearly, Federal incentives for renewable energy have had a major impact on wind energy development. Equally clear, however, is that progress in leading wind energy states is also heavily influenced by state programs promoting renewable energy, as well as state regulatory policies, regional considerations, and electricity infrastructure issues.

As markets evolve in the states and regions, pending Federal actions may have important implications for future wind energy development in the future. Among them: the renewal of the production tax credit (set to expire at the end of 2008); Federal Energy Regulatory Commission (FERC) facilitation of transmission capabilities for renewable energy; the passage of a Federal renewable portfolio standard; and changes in U.S. policy on global warming to limit carbon emissions. As important as these may be to long-term growth of wind energy, the primary issue affecting the short-term wind energy market in the two major wind energy states (Texas and California) is sufficient transmission capacity.

Issue in Focus: Central Station Solar Thermal Electricity Concentrating Solar Power Comes of Age

Introduction

Although solar energy provided only a miniscule portion of the Nation's power supply in 2006, the recent addition of central station solar capacity to the grid may be the beginning of a new wave of large solar power plants over the next four years. The following summarizes recent history, solar power technologies, and provides a short-term assessment of possible capacity increases.

The U.S. Southwest region is an ideal setting for solar thermal power. The deserts of Arizona, California, New Mexico, and Nevada have abundant sunshine and scarce rainfall. However, efforts to build utility-scale solar thermal power plants have been limited to 9 units built during the 1980's in the Mojave Desert of California, due to cost and performance issues (see Appendix). Known as the "Solar Energy Generating System" (SEGS), these units used parabolic troughs to capture the thermal energy from the sun directly to develop steam for producing electricity. (See: http://www.flagsol.com/SEGS tech.htm.)

Concentrating Solar Power—Background

Concentrating Solar Power (CSP) plants like SEGS are power plants that produce electricity from steam heated by the Sun's energy. Although the CSP concept has been around for decades, it was not considered economic and by the late 1990's was virtually ignored as a feasible electricity technology.

Recently, however, several factors have caused a resurgence of interest in CSP:

- The high cost of fossil fuels;
- Environmental concerns;
- Government incentives and mandates for renewable energy sources, such as renewable portfolio standards (RPS), which require electricity suppliers to source a certain percentage of electricity from renewable energy;
- Technological advances in CSP; and
- Short construction lead time.

Since the last SEGS unit was built in 1990, CSP technologies have been quietly attracting new attention. The Arizona Public Service's (APS) 1-megawatt (MW) Saguaro solar thermal power plant came online in December 2005, and the 64-MW Nevada Solar One went online in June 2007, demonstrating that utilities and investors are becoming interested in developing large-scale CSP plants.

Concentrating Solar Power—Technology

Concentrating solar power technologies, that utilize different kinds of mirror configurations to convert the Sun's energy into high-temperature heat, are used in CSP plants. The heat energy is then used to generate electricity in a steam generator. There are three main types of concentrating solar power technologies:

• Parabolic Trough: A parabolic trough system uses parabolic mirrors that line up in long rows to concentrate sunlight onto an absorber tube (receiver). The receiver contains a fluid that is heated and circulated, and the heat is released to generate steam. The steam powers a conventional steam generator to produce electricity (Figure 1.7).

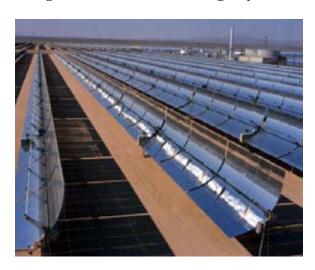

Figure 1.8. Parabolic Trough System

Source: National Renewable Energy Laboratory (NREL)

• **Dish/Engine:** A dish/engine system uses a mirrored dish to collect and concentrate sunlight onto a receiver. The receiver absorbs the sun's heat and transfers it to a gas or fluid in an engine. The heat causes the gas or fluid to expand and drive a piston, which is connected to a generator to produce electricity (Figure 1.8).

Figure 1.9. Dish/Engine System

Source: National Renewable Energy Laboratory (NREL)

• **Power Tower:** A power tower system utilizes a field of mirrors to concentrate and reflect sunlight to a receiver on the top of a centrally located tower. The receiver absorbs the sun's heat through molten salt, and the heat is released to generate steam. The steam powers a conventional steam generator to produce electricity (Figure 1.9).

Figure 1.10. Power Tower System

Source: National Renewable Energy Laboratory (NREL)

Concentrating Solar Power—Short-Term Outlook

CSP may be on the brink of significant growth. One sign for its potential growth is that utilities are mandated to increase their renewable portfolios (Figure 1.10). For example, the California RPS establishes a goal of 20 percent renewable generation by 2010. In addition, California Senate Bill SB1368 set a new standard for any new long-term financial contracts for electricity used in California. This standard prohibits California

utilities from building coal-fired power plants and/or procuring coal-produced electricity in and/or outside the state of California unless carbon capture and sequestration (CCS) technology is used. This standard will likely encourage the development of clean electricity generation technologies, which may include CSP technology. In addition, some states, such as Nevada and Arizona, have an RPS that requires a certain percentage of the renewables requirement to be fulfilled by solar resources.

Although California utilities are making progress toward meeting their 2010 RPS goals through the long-term power purchasing agreement process, a number of analysts in the country believe that California utilities will not achieve full compliance with their RPS requirements of 20 percent by 2010. However, California lawmakers nonetheless believe there is value in renewable energy technologies and are explicitly focusing on the new statutes and rules (such as RPS) that they believe will protect the environment and prevent future energy shortages.³⁴ Further, the state's electric entities are making significant commitments to new sources of renewable energy such as CSP.

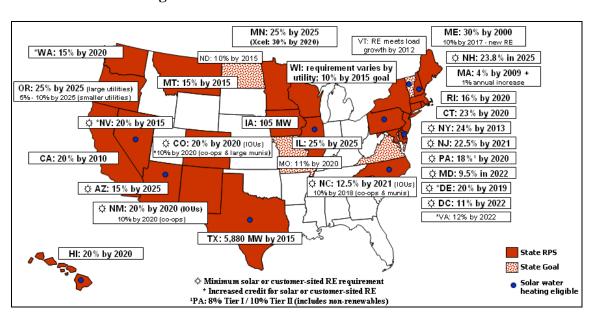

Figure 1.11. Renewables Portfolio Standards

Source: The Database of State Incentives for Renewables and Efficiency (DSIRE), November 7, 2007. See www.dsireusa.org.

Currently, California is considering an even higher goal of 33 percent RPS by 2020 as advocated by Governor Schwarzenegger.³⁵ All energy suppliers, including municipal utilities, energy service providers and community choice aggregators would meet the same renewable energy goals required of the investor-owned utilities. Achieving the 33 percent goal could have tremendous implications throughout California over the next ten

³⁴ Section 387 of the California Public Utility code requires the PUC to implement and enforce the RPS, "while taking into consideration the effect of the standard on rates, reliability, and financial resources and the goal of environmental improvement."

³⁵ See http://docs.cpuc.ca.gov/word_pdf/misc/Achieving_33_Percent_RPS_Report.pdf.

years. Under the Governor's directive, the California Public Utilities Commission and the California Energy Commission are now developing plans to address the goal of 33 percent RPS by 2020.

Concentrating Solar Power--Projects

Several energy companies that have acquired the proven CSP technology have indicated their intention to enter the CSP market. These companies have unveiled plans for utility-scale solar thermal projects in California and other areas. If constructed as planned, these plants could deliver more than 3,000 megawatts of renewable power to the energy-hungry Southwest region within approximately four years.

The following provides an overview of the completed and proposed CSP projects over the past few years. ³⁶

Completed CSP Projects

Saguaro Solar Thermal Power Plant (April 2006)

- Who: Arizona Public Service Company (APS)
- What and When: In 2002, APS contracted with Solargenix Inc. to construct and provide the solar thermal technology for a one megawatt parabolic trough plant. Construction began in June 2004 and was completed 15 months later. The plant has been generating electricity since December 2005.
- Where: The plant was built on a patch of desert in Red Rock, next to the existing Saguaro Power Plant, about 30 miles north of Tucson.
- Why: APS had to meet the goals of the Arizona Corporation Commission's Environmental Portfolio Standard, which, at the time, required APS to generate 1.1 percent of its energy through renewable sources by 2007 with 60 percent of this through solar resources.

Nevada Solar One (June 2007)

- Who: Acciona Energy
- What: Acciona Energy announced that Nevada Solar One, a 64-megawatt solar thermal power plant near Boulder City, Nevada, is now online. The new facility is the largest of its type to be built in the world since 1991. The electricity generated by the plant will be purchased by Nevada Power Company and Sierra Pacific Power under a 20-year power purchase agreement.
- When: Groundbreaking took place in February 2006. The plant was constructed rapidly and on schedule and was completed in just over a year.

³⁶ "Proposed" refers as projects that have been publicly announced in the news media. It does not necessarily mean a CSP plant will actually be built. In some cases, proposed plants have received regulatory approval and/or secured financing.

- Where: The plant is located in the Nevada desert on a site directly adjacent to the existing 480 MW El Dorado Energy combined cycle natural gas power plant. It covers 400 acres and consists of 760 parabolic trough concentrators.
- **Why:** Support by Nevada Power Company and Sierra Pacific Power Company needed to meet part of their renewable energy portfolio standard requirement.

Proposed CSP Projects

Proposed Stirling Solar Thermal One (October 2005)

- Who: Stirling Energy Systems, Inc.
- What: The California Public Utilities Commission has approved a renewable contract for Southern California Edison. The 20-year power purchase agreement calls for the development of a 500 MW solar power project using Stirling dish technology. The agreement includes an option to expand the project to 850 MW and will count toward Southern California Edison's Renewable Portfolio Standard (RPS) requirements.
- When: Stirling will build a one megawatt test facility using 40 of the company's 37-foot diameter dish assemblies. Subsequently, a 20,000-dish array is planned to be constructed from January 2009 to December 2012.
- Where: A 4,500-acre site in San Bernardino County, California.
- Why: This helps to fulfill the RPS requirement for utilities to get 20 percent of their electricity from renewable sources by 2010.

Proposed Stirling Solar Thermal Two (December 2005)

- Who: Stirling Energy Systems, Inc.
- What: San Diego Gas and Electric Company has announced that the California Public Utilities Commission has approved its contracts to purchase 300 megawatts of solar power, with the potential to grow to 900 MW from Stirling's Solar Thermal Two facility.
- When: To be announced.
- Where: Stirling plans to build an array of Stirling solar dishes on a 1,920-acre site in California's Imperial Valley.
- Why: California RPS.

Proposed Victorville 2 Hybrid Power Project (February 2007)

- Who: City of Victorville, CA
- What: The City of Victorville has filed an application with the California Energy Commission to construct and operate the Victorville 2 Hybrid Power Project, including 513 MW from natural gas and 50 MW from solar thermal.
- When: Construction of the project was scheduled to start in the summer of 2008, and full commercial operation is expected to begin by late summer 2010.
- Where: City of Victorville in San Bernardino County, California.

• Why: California RPS.

Proposed Mojave Solar Park 1 (July 2007)

- Who: Solel Inc.
- What: Pacific Gas and Electric Company has entered into a 25-year renewable energy agreement with Solel to purchase renewable energy from the Mojave Solar Park. The 553 MW solar plant, estimated to cost \$2 billon, will use solar thermal parabolic trough technology.
- When: Construction will begin in 2009 and the plant will start generating electricity in 2011.
- Where: It is to be located on a 6,000-acre site in the Mojave Desert.
- **Why:** California RPS.

Proposed Ivanpah Solar Project (September 2007)

- Who: BrightSource Energy
- What: BrightSource Energy Inc. has filed an application with the California Energy Commission to develop a 400 MW solar power project in the Mojave Desert. The project consists of three solar plants that use Distributed Power Tower (DPT) solar field technology developed by Luz II, a wholly-owned subsidiary of BrightSource Energy.
- When: The plants are proposed to be built in three phases. Construction of the first, a 100-MW plant, will begin in the first quarter of 2009, with commercial operations starting in the fourth quarter of 2010. The second 100-MW plant will break ground in 2010 and is expected to begin commercial operations in 2011. Construction of the third, a 200-MW plant, will begin in 2011 with commercial operation expected by the end of 2012.
- Where: Three separate locations in Southern California's Mojave Desert, near the Nevada border.
- Why: California RPS.

Proposed Solar Power Plant (September 2007)

• Who: FPL Group

- What: A \$2.4 billion investment, including \$1.5 billion for a 300 MW solar thermal plant in Florida and an additional 200 MW solar thermal plant tentatively slated for California.
- When: Construction of a 10-MW solar power plant with Ausra's solar thermal technology is proposed to begin in 2008. If it meets performance expectations, the remaining 290 megawatts will follow within three years. A total of 300 megawatts capacity could be available by 2011.
- Where: The specific locations have not been chosen.
- Why: The plant is part of FPL's stated goal to add at least 600 MW of new solar generating capacity by 2015.

Proposed Carrizo Energy Solar Farm (September 2007)

- Who: <u>Carrizo Energy, LLC</u>
- What: Carrizo Energy, LLC has proposed to build the Carrizo Energy Solar Farm with production up to a nominal capacity of 177 MW.³⁷
- When: Construction from site preparation to full commercial operation is expected to take approximately 35 months. If site construction activities commence in the first quarter of 2009, the entire project could be completed by the first quarter of 2012.
- Where: The site is located in eastern San Luis Obispo County, California.
- **Why:** California RPS.

Proposed Kern Solar Plant (October 2007)

- Who: Solar MW Energy Inc. (SME) and affiliate Ecosystem Solar Electric Corp. (ESE)
- What: ESE has commenced the development of a solar thermal electric combined cycle hybrid power plant (nominal capacity of 109.4 MW). The proposed plant utilizing solar energy as well as hybrid combined cycle co-fired and gas-fired superior systems will cost \$100 million to build. The latest design of improved tried-and-true CSP technology for solar energy, consisting of twin parabolic collectors with twin parabolic tubes receivers, will be implemented.
- When: ESE has sent official notices to Federal, State and local governments involved in the permitting of the proposed plant.
- Where: A 40-acre site in Kern County, California.
- **Why:** California RPS.

Proposed Barstow Solar Plant (October 2007)

- Who: Solar MW Energy Inc. (SME) and affiliate Ecosystem Solar Electric Corp. (ESE)
- What: ESE has proposed the development of another solar thermal electric combined cycle hybrid power plant (nominal capacity of 59.4 MW).
- When: The project is still in design stage.
- Where: A 54-acre site near Barstow in San Bernardino County, California, is planned.
- Why: California RPS.

³⁷ Nominal capacity of unglazed flat plate collectors is the instantaneous thermal output of the collector under established operating conditions.

Conclusion

California's utilities are under mandate to increase the percentage of their sales from renewable energy resources. To meet California's RPS requirements, California has established standards and guidebooks for utilities in contracting for eligible renewable energy resources, implementing rules for compliance (such as applying excess renewable procurement in one year to a deficit in another year), and imposing penalties for non-compliance. Noticeably, there are hurdles to achieve a 20 percent RPS by 2010 by using CSP, such as:

- Utilities may have signed long-term power purchase agreement with companies that planned to build solar thermal power plant with technologies that are not yet fully commercialized;
 - Construction permit issues for large-scale CSP plants; and
- The availability of the funding for above market costs covered by California's Renewable Resource Trust Fund.

As California's utilities move toward the 20 percent RPS goal by 2010, there may be an environment in which solar thermal power plants can reemerge as significant renewable electricity producers. The mandates to increase reliance on renewable energy have changed the utilities' long-term power purchases planning, which in part, is the key factor supporting the recent demand for large-scale solar thermal power plants. This key factor is similar to the driving force behind the demand for the initial SEGS units in 1983 discussed below, when Luz International, Ltd. negotiated a 30-year contract with Southern California Edison to sell electricity from its plants (See Appendix). Just as with the ups and downs of the CSP industry two decades ago, it is likely that the rebirth of the CSP industry will depend as much on the actions of utilities and state regulators as on development of industry technology.

Appendix: Early History

In the 1980's, Luz International, Ltd., began to build a series of Solar Energy Generating Systems (SEGS) in California's Mojave Desert. A total of nine separate SEGS plants have been constructed by Luz. The first plant was commissioned in 1984 and the last was commissioned in 1990 (Table 1.H2). Under Federal guidelines, the SEGS plants can rely on natural gas for up to 25 percent of their power supply and still qualify as a renewable resource.

In 1991, Luz ran into financial trouble and filed for Chapter 7 bankruptcy after failing to secure construction financing for its tenth SEGS plant. The operation of the SEGS plants was taken over by an investor group. Luz failed largely due to natural gas prices and electricity costs not rising as much as expected. The problem was compounded by operating and maintenance costs for the station not declining as rapidly as had been expected, and uncertainty about, or expiration of, key tax incentives. The tenth SEGS plant was never constructed.

Table 1.H2 U.S. Operating Solar Electric Generating Systems (SEGS)

Plant Name	SEGS I	SEGS II	SEGS III	SEGS IV	SEGS V	SEGS VI	SEGS VII	SEGS VIII	SEGS IX
State	CA								
Prime Mover	Steam Turbine								
Nameplate Capacity (MW)	13.8	30.0	34.2	34.2	34.2	35.0	35.0	92.0	92.0
Summer Capacity (MW)	13.8	30.0	36.0	36.0	36.0	36.0	36.0	88.0	88.0
Winter Capacity (MW)	13.8	30.0	34.0	34.0	34.0	35.0	35.0	64.0	64.0
Status	Operating								
In-Service Year	1984	1985	1986	1986	1987	1988	1988	1989	1990
Primary Energy Source	Solar (Thermal)								
Secondary Energy Source	Natural Gas								

Source: Energy Information Administration (EIA)

These SEGS plants reliably generate electricity in the Mojave Desert. The development of the SEGS project occurred between 1984 and 1990 following a decade which witnessed two major increases in petroleum prices and oil shortages. After that time, average energy prices stabilized, supply remained readily available, and the demand for SEGS plants diminished. However, in the last several years, increasing dependence on foreign oil, environmental issues, and rising energy prices have sparked a rapidly growing interest in alternate energy sources, including solar.

Issue in Focus: Biodiesel in the Energy Supply

Introduction

While the effort to reduce dependency on foreign oil in the transportation sector has focused on a replacement for gasoline, efforts have also been underway to find a suitable replacement for diesel fuel. In 1999, the United States began commercial production of a diesel fuel substitute, generally made from soybean and canola oil, known as biodiesel.

Though biodiesel currently represents only a small fraction of the diesel fuel market, it is of great interest as a diesel replacement because of two specific fuel characteristics. First, biodiesel can be used in any diesel engine and therefore its usage usually does not require modifications to the on-board fuel system.³⁸ Second, the combustion of biodiesel emits lower levels of several pollutants compared with traditional diesel.

From a marketing perspective, getting biodiesel into the mainstream distribution system is likely to be much easier than getting E85 into the gasoline distribution system. There are far fewer major retail diesel facilities (mainly truck stops), and unlike branded service stations for motor gasoline, retail diesel facilities are usually not restricted in the non-branded fuels they can sell, thus making biodiesel marketing easier. ³⁹

What is Biodiesel?

Biodiesel is a renewable-based diesel fuel substitute, made from vegetable oils or animal fats, which meets the requirements of American Society for Testing & Materials (ASTM) Standard D 6751. 40 Because biodiesel has the properties of petroleum-based diesel, it can be used as a substitute for diesel, either pure or blended with petroleum diesel in any percentage. 41 When biodiesel and petroleum diesel are combined, the resultant blend is named by its volume percentage of biodiesel. For example, a blend of 20 percent biodiesel with 80 percent petroleum diesel is known as B20. Pure or straight biodiesel is known as B100 or neat biodiesel.

How is Biodiesel Produced?

³⁸ If biodiesel blends of greater than 20 percent biodiesel are used, then minor adjustments to the engine may be required.

³⁹ Recently, however, Section 241 of The Energy Independence and Security Act of 2007 (P.L. 110-140) amended the Petroleum Marketing Practices Act to prohibit a franchisor (i.e. oil company) from restrict ing a franchisee from installing E85 infrastructure through a franchise agreement.

⁴⁰ Some entities include so-called "renewable" or "green" diesel in their definition of biodiesel. "Renewable" or "green" diesel includes processed raw vegetable oils or fats that have not been chemically transformed into esters. EPACT05 distinguishes between "biodiesel" and "renewable diesel." See http://www.biodiesel.org/resources/definitions/default.shtm for further explanation.

⁴¹ Some alterations may need to be made to older engines in order to run on blends with high percentages of biodiesel.

Biodiesel is produced by a trans-esterification process in which oils or fats are mixed with a catalyst and an alcohol. This chemical reaction produces trigylcerides⁴², which are then split apart and recombined to make methyl esters 43 (biodiesel) and crude glycerin 44 as a co-product. The glycerin is generally further distilled to a higher purity and then sold for use in the pharmaceutical and cosmetics industries.

The oil or fat from which biodiesel is made can come from many sources, including but not limited to the following: canola oil, palm oil, sunflower oil, soybean oil, animal tallow, lard and yellow grease (recycled grease).

Currently, soybean oil is the dominant feedstock in the United States due to its availability and historically low cost. However, in recent years an increasing amount of biodiesel has been produced from waste grease or rendered animal fat due to increasing prices of soybean oil. Biodiesel can also be made from the trans-esterification of hydrocarbons which are derived from agricultural products such as rice hulls or other carbonaceous stock.

What are the Characteristics of Biodiesel?

Biodiesel contains approximately 86 percent the heat content of Ultra Low Sulfur Diesel (ULSD), meaning that customers can use low level blends of biodiesel without noticing a significant decrease in mileage (Table 1.H3). The flash point (the temperature which a liquid needs to exceed in order to self-ignite) of biodiesel is substantially higher than ULSD, meaning that biodiesel is much less hazardous to contain and transport than is ULSD. The pour point of a liquid is the lowest temperature at which it is still a lowviscosity "pourable" liquid, and the cloud point is the temperature at which dissolved solids begin to precipitate out of the liquid. Because biodiesel is produced from fatty acids, any incompletely reacted materials left in the solution cause it to have both a higher pour and cloud point than ULSD. High cloud and pour points only become an issue in extremely low temperatures, as the fuel may become viscous and need to be warmed before usage.

One final point of comparison between biodiesel and ULSD is the sulfur content biodiesel that meets ASTM Spec D 6751 has 0 parts per million (ppm) sulfur by definition; however, it may pick up miniscule amounts of sulfur while it is being transported and distributed⁴⁵. Because sulfur is considered to be harmful to human health when emitted into the atmosphere, starting in 2006 the Environmental Protection Agency mandated that sulfur levels for all on-road diesel fuel must be reduced from 500 ppm to 15 ppm. Although this mandate reduced the pollution created from ULSD, it has been problematic for large diesel engines because it also reduced the lubricity of the fuel,

⁴² Fats composed of three fatty-acid chains linked to a glycerol molecule

⁴³ Biodiesel produced via a reaction between fatty acids and methanol

⁴⁴ A clear, odorless, viscous sugar alcohol that is a by-product of the trans-esterification process for

producing biodiesel.

45 Sometimes biodiesel is transported in vehicles or pipes that previously contained ULSD, and residual sulfur from the prior fuel may be transferred to the biodiesel.

which is important in maintaining an engine's performance. Biodiesel is a natural lubricant, and blending it into ULSD has the effect of both reducing the sulfur content and increasing the lubricity.

Table 1.H3 Physical Characteristics of Biodiesel vs. Ultra Low Sulfur Diesel (ULSD)

	Biodiesel (soybean)	Ultra Low Sulfur Diesel
Heat Content (Btu/gallon)	118,952	139,000
Flash point (°C)	93	>52
Pour Point (°C)	0	-27
Cloud Point (°C)	2	-23
Sulfur (ppm)	0-2	<15

Who Produces Biodiesel?

The biodiesel production industry spans the spectrum from small seasonal operations to plants operated by large multinational conglomerates. Plant sizes (measured in gallons per year of capacity) range from 300,000 to 100,000,000 gallons per year. Because biodiesel can be made from multiple feedstocks, the production industry is not as geographically constrained as other biofuels industries, which are limited to fewer locations. Pockets of concentrated biodiesel plants exist in the Midwest, the South and Texas, but in general production is dispersed throughout the country.

Just as production facilities vary in size, biodiesel companies also vary in their business models and how they market their product. All biodiesel plants necessarily produce pure biodiesel (B100), but some plants sell only this product, while others sell a wide range of biodiesel blends for the transportation fuels market. Due to the complicated nature of the petroleum diesel distribution market, producers have many options in how they move their product. For example, producers can co-locate a biodiesel pump with their production facility to allow consumers to directly fuel their vehicles on-site. Some producers sell strictly to wholesalers or distributors, while other producers sell to fleets and school districts. Biodiesel is even sold outside the transportation sector, notably to home heating oil companies.

Biodiesel can leave the plant by individual vehicle, tanker truck, train or barge, depending on both the location of the plant and the destination of the product. In addition to local domestic markets, anecdotal evidence suggests that biodiesel is being exported to Europe in response to demand created by renewable fuels blending mandates in certain European countries. Partially due to high demand caused by European subsidies, U.S. biofuels command a higher price in European markets than they do in domestic markets. Federal biodiesel blending credits (which can be taken regardless of the biofuel's end destination) combined with high prices in Europe means that producers and distributors can increase their revenues by selling the biodiesel into European markets rather than domestic ones.

How is Biodiesel Used?

Biodiesel's primary use is as a fuel for onroad vehicles (principally trucks), but it also has several uses in other markets. It is used in offroad transportation and industrial applications, such as marine engines, mining equipment, agricultural equipment, and stationary diesel engines and generators. Additionally, biodiesel has properties of a mild solvent and is sometimes sold as such; for example, it can be used in distributing pesticides through agricultural irrigation systems. Biodiesel has excellent lubricating properties and virtually no sulfur content, which makes it a popular additive for new low and ultra-low sulfur diesel fuels.⁴⁶ Biodiesel can also be blended into home heating oil or used as substitute heating oil at the B100 level.

What Factors Have Influenced the Biodiesel Industry in Recent Years?

The biodiesel industry has undergone massive growth in the last five years and is poised to continue to grow into the foreseeable future. Production has grown from 204 thousand barrels in 2001 to 5,963 thousand barrels in 2006. One important driver of this growth has been Federal incentives to producers and blenders of biodiesel. In 2004, The American Jobs Creation Act established tax credits of \$1.00 per gallon produced for agribiodiesel and renewable diesel, and \$.50 per gallon for waste-grease biodiesel. If the fuel is used in a mixture, the credit is 1 cent per percentage point of agri-biodiesel used or 1/2 cent per percentage point of waste-grease biodiesel. Additionally, the Energy Policy Act of 2005 (EPACT2005) created the Small Biodiesel Producer Tax Credit, which allows for an additional production credit equal to \$.10 per gallon on the first 15 million gallons of agri-biodiesel produced at facilities with annual capacity not exceeding 60 million gallons per year.

Another piece of legislation affecting the growth of the biodiesel industry is the Renewable Fuels Standard Program established by EPACT2005. This program

⁴⁶ Regulations limiting the sulfur content of diesel fuel became effective in 2006. The lubricity of petroleum diesel has been reduced due to the processes used to reduce sulfur and aromatic compounds in the fuel (http://www.cleanairfleets.org/altfuels.html)

⁴⁷ Energy Information Administration, Monthly Energy Review April 2008 (Washington, D.C. April 2008, Table 10.4, http://tonto.eia.doe.gov/FTPROOT/multifuel/mer/00350804.pdf

⁴⁸ Energy Policy Act of 2005 (Section 1344) extended the tax credit for biodiesel blenders through 2008.

mandated a certain level of renewable fuels to be blended into the gasoline and diesel fuels sold in the U.S⁴⁹. In 2004, this level was approximately 4 billion gallons and in 2012 it was to reach 7.5 billion gallons. After 2012, the blending requirement was to grow at a rate equal to the growth of gasoline consumption. The renewable fuels considered under this mandate are ethanol and biodiesel. It is left up to the individual refiners to use whichever renewable fuel makes the most economic sense in their particular operations, as long as the overall standards are met yearly.

Other factors influencing the market have been higher petroleum prices and continued Federal support for alternative fuels, shown in recently enacted Federal legislation. Also, EPA's mandate that diesel consumed in the U.S. be ultra-low sulfur diesel (ULSD) as of October 15, 2006 has been an additional driver of biodiesel consumption. Because of biodiesel's extremely low⁵⁰ sulfur content, blends of biodiesel with petroleum diesel have been instrumental in the transition from low sulfur diesel to ULSD, which has also helped create a biodiesel distribution network that is necessary for continued expansion of the industry. Two other mandated-purchasing programs helping to create demand for biodiesel are Federal fleet purchases, and state-level fuel pool blending requirements, such as those recently enacted in Minnesota and Washington. Finally, foreign demand for biodiesel continues to increase because of country-specific biofuels usage requirements. There is currently no statistical data on the amount of biodiesel exported by the United States, but anecdotal evidence suggests a fair amount of U.S. production is being exported to Europe.

What is the Outlook for Biodiesel?

EIA's Annual Energy Outlook 2008 reference case predicts that consumption of biodiesel will continue to grow over time due to continued and increasing demand for the fuel, both in its pure form and in its many blend levels. The Energy Independence and Security Act (EISA) of 2007 is an important new factor in biodiesel's demand equation. It was enacted in December 2007 and affects the biodiesel industry in two significant ways. First, the bill seeks to promote increased consumer confidence in biodiesel fuel quality by requiring more stringent fuel labeling requirements. Second, Section 202 of the EISA 2007 expands the mandatory usage of biodiesel under the Renewable Fuel Standard. By calendar year, the bill requires the introduction of the following amounts of biodiesel into the transportation fuel stream:

```
2009— 500,000,000 gallons
2010— 650,000,000 gallons
2011— 800,000,000 gallons
2012—1,000,000,000 gallons
```

Released: July 2008

⁴⁹ EPACT2005 blending levels have been superseded by new blending levels mandated by the Energy Independence and Security Act of 2007.

⁵⁰ Biodiesel by definition has sulfur content of less than 0.02%. If the finished fuel contains any additional sulfur, it is most likely a product of the transportation process.

Issue In Focus: Wave and Tidal Energy

Introduction

The United States has abundant ocean wave and tidal energy resources. It is estimated that if one-quarter of the U.S. wave resource were harnessed at 50 percent efficiency, the electricity produced would be roughly equivalent to electricity produced from hydropower in 2003. This translates to about 6.8 percent of the total amount of net electricity generated in the United States in 2006. The states in 2006.

Research and development (R&D) funding for Ocean Energy Systems was included in the Department of Energy's initial year of operation, fiscal year (FY) 1978, and continued through FY 1994. The budget for Ocean Energy Systems was then zeroed out through FY 2008. The Department of Energy Hydropower Program was closed out in FY 2006 and resurrected in FY 2008 as the Water Power Program. The mission of the program is to "explore, test and develop (as appropriate) innovative and effective technologies capable of harnessing hydrokinetic (i.e., energy from the motion of fluids) energy resources, including ocean wave and current (ocean and tidal) energy)." Encouraged by the Energy Policy Act of 2005 (EPACT) and the Energy Independence and Security Act of 2007, much of this activity has been spawned by the adoption of Renewable Portfolio Standards (RPS). In fact, 17 of the 22 coastal states have an RPS and each one that does includes tidal energy and wave energy technologies as eligible for meeting the state's renewable standard or goal.

Given the demonstration and pilot projects that are beginning or already in operation, and the significant amount of the resource and power potential, identifying and following this market is important to our understanding of the overall energy picture.

Jurisdictional Issues⁵⁷

The Federal Energy Regulatory Commission (FERC) is responsible for regulating nonfederal development of hydropower and hydrokinetics, which it defines as "hydroelectric generation from ocean waves, tides, and currents and from free-flowing rivers." There is some ambiguity over regulatory jurisdiction since the Energy Policy Act of 2005 gave the Department of Interior Minerals Management Service (MMS) oversight authority for renewable energy projects on the Outer Continental Shelf (OCS). The OCS begins three miles off shore, except for Texas and the Gulf Coast of Florida, where it begins 10 miles off shore. Therefore, inside these limits there is no ambiguity about FERC's jurisdiction. 60

As part of its regulatory function, the commission issues preliminary permits and licenses to hydrokinetic project developers. A preliminary permit, issued for up to three years, holds a place in the licensing queue while the project site is being studied; it does not authorize construction. In fact, a permit is not a prerequisite for a license. A license is for a 30 to 50 year period and conveys the right of eminent domain, that is, the project developer owns the rights to the land or waterway on which the project is being developed. In November 2007, FERC released a policy statement which allows it to issue conditioned licenses. A conditioned license can be awarded even though certain authorization required from other entities may be outstanding. It assists the developer in obtaining project financing even though it does not allow construction. As of January 24, 2008, 49 permits had been issued and 26 were pending. As of December 31, 2007, one license had been issued, and none were pending.

Technologies

Water is a very good energy source due to its wide availability and has high energy potential because of its comparatively high density. It is also renewable and emission-free when used in electricity generation. While tides are intermittent, they are very dependable, running in one direction for hours and then reversing. Waves are fairly predictable days in advance, making system supply planning somewhat easier than with

wind power - another intermittent renewable technology.⁶⁴ However, the ocean environment is very stressful on equipment and until recently very few projects had been undertaken.

There are a number of different wave and tidal energy devices either being used or in the planning stages. They can be grouped into two broad categories: surface devices and instream turbines

Wave Energy Technologies^{65,66}

The primary wave energy technologies are:

- Terminator device: a structure that extends perpendicular to the direction of wave travel. An example of a terminator is the oscillating water column (OWC). In an OWC, water enters a subsurface chamber with air inside. The action of the waves causes water in the chamber to act as a piston, forcing the air trapped above it through an opening to drive a turbine-generator.
- Attenuators: long, floating structures that extend parallel to the direction of wave travel. The waves cause the device to flex. The flexing motion drives hydraulic pumps or other energy converters.
- Point absorber: a floating structure with components that move relative to each other due to wave action. This relative motion is used to drive electromechanical or hydraulic energy converters.
- Overtopping device: consists of a structure over which waves fall into a reservoir with hydro turbines installed at the bottom. The water turns the turbines as it goes back out to sea. The turbines power generators that produce electricity.
- Wave rotor: a turbine that is turned directly by waves and is coupled to a generator to produce electricity.

Tidal Energy Technologies^{67,68}

Tidal energy technologies include:

- Turbines: submerged horizontal- or vertical-axis devices turned by the power of tides. The turbines are coupled to a generator or other energy converter.
- Reciprocating tidal stream devices: systems in which hydrofoils move perpendicular to the tidal stream. These hydrofoils act as pistons which drive a hydraulic motor and generator to produce electricity.
- Barrage: a dam built with gates and turbines. As tides produce a difference in water levels on either side of the dam, the gates are opened and water flows through the turbines which turn an electric generator to produce electricity.
- Venturi effect device: tidal flow is constricted by being directed through a duct, thereby causing a pressure difference, which, in turn, causes a secondary fluid to flow through a turbine which turns an electric generator to produce electricity.

Environmental Issues

Wave and tidal energy devices produce no greenhouse gases when generating electricity. Also, the devices operate beneath or close to the surface and are, generally, not visible from shore. It is expected that wave energy devices will only minimally affect the size of waves. Similarly, tidal stream devices will only extract a small amount of the energy available, thereby not unduly affecting the nearby environment. However, there are environmental considerations. To that end, in October 2005, the Department of Energy convened a workshop to identify important environmental issues associated with hydrokinetic technologies, as well as mitigation strategies. The environmental issues noted include the following: alteration of river/ocean bottom; suspension of sediments and contaminants; danger that aquatic animals may be struck or entangled; electromagnetic fields may attract, deter, or injure aquatic animals; protection of near-shore vegetative environments; wave and current buffering; potential noise effects.

Current Activities in the United States

There are a number of on-going wave and tidal pilot projects in the United States. The Electric Power Research Institute (EPRI) has an active ocean energy program and supports a number of demonstration projects. ⁷² These include six wave energy projects in states on both coasts and Hawaii and tidal energy projects on both coasts and in Canada. EPRI sees wave power as being a cost competitive power source in the 2020 time period.

The first major tidal project in the United States dates back to 2002, when Verdant Power Company began its Roosevelt Island Tidal Energy (RITE) project in New York City's East River. Using six "Free Flow" turbines (35 kilowatts installed capacity each) to generate electricity, power has been transmitted to an end-use customer. ⁷³ This project requires no impoundment or dams and operates completely underwater. The project expects to receive the necessary permits and licenses for commercial operation by the end of 2008 and to potentially expand to 10 megawatts by 2010, depending on the successful demonstration of its first six turbines. 74 75

On December 20, 2007, FERC issued its first license for a hydrokinetic energy project – the Makah Bay Offshore Wave Pilot Project, which will be located in the Pacific Ocean off the coast of Washington. The licensee is Finavera Renewables Ocean Energy, Ltd. The license includes mitigation measures to protect the environment. ⁷⁶ The project is planned as a 1 megawatt demonstration plant – enough to power about 150 homes.

Obstacles to Development

Hydrokinetic devices are relatively unproven and use new technologies that have not yet established a track record. Investors prefer certainty and until more experience is gained, financing might be problematic or relatively expensive. There are also environmental and land use issues associated with these projects, and demonstration projects don't necessarily foretell what may occur when they are built full scale. In addition, there is the economic obstacle of whether the power from wave and tidal sources will be cost competitive with competing sources of energy.

International Projects

Hydrokinetic power projects are recent and few. Consequently, learning from similar projects is very important from a developmental, operational, economic and environmental perspective. This learning is likely to convey across projects no matter

where they are developed. In order to facilitate the transfer of information across projects, in October 2001, the International Energy Agency (IEA) instituted an Implementing Agreement on Ocean Energy Systems (OES). This is a framework for international collaboration on activities to enhance the commercialization of ocean energy systems which include wave and tidal power. The principal tasks of this agreement are: 1) review, exchange and disseminate information on ocean energy systems; 2) develop recommended practices for testing and evaluating ocean energy systems; and 3) integrate ocean energy plants into transmission and distribution networks.

The world's first tidal power plant was built at La Rance, in northwestern France in 1966 and was connected to the French grid in December 1967.^{78 79} The plant consists of a barrage, or dam, and twenty-four 10 megawatt bulb-type turbines.⁸⁰ It has been operating without major incident for over 30 years and produces enough power to supply a city of 300,000 people.

A sampling of other projects being developed worldwide is instructive for the kinds of technologies that are being developed and used and any problems they may be encountering (see below).

Conclusion

Tidal and wave energy projects are being developed worldwide. Two major organizations – the Electric Power Research Institute and the International Energy Agency – have programs in place to support this emerging industry. At a time when global climate change and sustainable energy are global concerns, these renewable, relatively benign sources of power are potentially important additions to the world's power supply options.

a Includes supplemental gaseous fuels.

a Includes supplemental gaseous fuels.

b Petroleum products supplied, including natural gas plant liquids and crude oil burned as fuel.

c Biomass includes: biofuels, waste (landfill gas, MSW biogenic, and other biomass), wood and wood-derived fuels.

MSW=Municipal Solid Waste.

Note: Ethanol is included only in biofuels. In earlier issues of this report, ethanol was included in both petroleum and biofuels, but counted only once in total energy consumption. Totals may not equal sum of components due to independent rounding. Sources: Non-renewable energy: Energy Information Administration (EIA), Monthly Energy Review (MER) March 2008, DOE/EIA-0035 (2008/3) (Washington, DC, March 2008,) Tables 1.3, 1.4a and 1.4b. Renewable Energy: Table 1.2 of this report.

- a Biodiesel primarily derived from soy bean oil.
- b Difference between the energy in biodiesel feedstocks (principally soy bean oil) and the energy in biodiesel consumed in the transportation sector.
- c Ethanol primarily derived from corn.
- d Difference between energy in ethanol feedstocks (primarily corn) and its coproducts (wet and dry distiller grains), and the energy in ethanol consumed in the transportation sector.
- e Includes paper and paper board, wood, food, leather, textiles and yard trimmings.
- f Agriculture byproducts/crops, sludge waste, and other biomass solids, liquids and gases.
- g Wood and wood pellet fuels.
- h Includes small amounts of distributed solar thermal and photovoltaic energy used in the commercial, industrial and electric power sectors.
- i Black liquor, and wood/woodwaste solids and liquids.
- j The electric power sector comprises electricity-only and combined-heat-power (CHP) plants within North American Classification System (NAICS) 22 category whose primary business is to sell electricity, or electricity and heat, to the public. PV=Photovoltaic.
- MSW=Municipal Solid Waste.
- *=Less than 500 billion Btu.
- NA=Not Applicable.

Note: Data revisions are discussed in the Highlights section. Revisions to biomass removed MSW non-biogenic and tires from renewable waste energy. Totals may not equal sum of components due to independent rounding.

Sources: Analysis conducted by Energy Information Administration, Office of Coal, Nuclear, Electric, and Alternate Fuels and specific sources described as follows. Residential: Energy Information Administration, Form EIA-457A/G, "Residential Energy Consumption Survey;" Oregon Institute of Technology, Geo-Heat Center; and Energy Information Administration, Form EIA-63-A, "Annual Solar Thermal Collector Manufacturers Survey" and Form EIA-63B, "Annual Photovoltaic Module/Cell Manufacturers Survey." Table 1.4. Renewable Energy Consumption for Nonelectric Use by Energy Use Sector and Energy Source, 2002-2006 (Quadrillion Btu)

Sector/Source	2002	2003	2004	2005	2006
---------------	------	------	------	------	------

- a Biodiesel primarily derived from soy bean oil.
- b Difference between the energy in biodiesel feedstocks (principally soy bean oil) and the energy in biodiesel consumed in the transportation sector.
- Ethanol primarily derived from corn.
- d Difference between energy in ethanol feedstocks (primarily corn) and its coproducts (wet and dry distiller grains), and the energy in ethanol consumed in the transportation sector.
- Includes paper and paper board, wood, food, leather, textiles and yard trimmings.
- f Agriculture byproducts/crops, sludge waste, tires, and other biomass solids, liquids and gases.
- g Wood and wood pellet fuels.
- h Includes small amounts of distributed solar thermal and photovoltaic energy used in the commercial, industrial and electric power sectors.
- i Black liquor, and wood/woodwaste solids and liquids.
- J The electric power sector comprises electricity-only and combined-heat-power (CHP) plants within North American Classification System (NAICS) 22 category whose primary business is to sell electricity, or electricity and heat, to the public. PV=Photovoltaic.
- MSW=Municipal Solid Waste. *=Less than 500 billion Btu. NA=Not Applicable.

Note: Data revisions are discussed in the Highlights section. Revisions to biomass removed MSW non-biogenic and tires from renewable waste energy. Dash indicates the sector has no data to report for the energy source for that year. Totals may not equal sum of components due to independent rounding.

independent rounding.

Sources: Analysis conducted by Energy Information Administration, Office of Coal, Nuclear, Electric, and Alternate Fuels and specific sources described as follows. Residential: Energy Information Administration, Form EIA-457A/G, "Residential Energy Consumption Survey;"

Oregon Institute of Technology, Geo-Heat Center; and Energy Information Administration, Form EIA-63-A, "Annual Solar Thermal Collector Manufacturers Survey" and Form EIA-63B, "Annual Photovoltaic Module/Cell Manufacturers Survey." Commercial: Energy Information Administration, "Form EIA-920, "Combined Heat and Power Plant Report;" and Oregon Institute of Technology, Geo-Heat Center. Industrial: Energy Information Administration, Form EIA-846 (A, B, C) "Manufacturing Energy Consumption Survey," Form EIA-920, "Combined Heat and Power Plant Report;"

Oregon Institute of Technology, Geo-Heat Center; Government Advisory Associates, Resource Recovery Yearbook and Methane Recovery Yearbook;

U.S. Environmental Protection Agency, Landfill Methane Outcach Program estimates; and losses and convolucts from the products of U.S. Environmental Protection Agency, Landfill Methane Outreach Program estimates; and losses and coproducts from the production of biodiesel and ethanol calculated as the difference between energy in feedstocks and production. Biofuels for Transportation: Biodiesel: 2001-2005: U.S. Department of Agriculture, Commodity Credit Corporation, Bioenergy Program estimates of production assigned to consumption and 2006 and forward: U.S. Department of Commerce, Bureau of Census, Current Industrial Reports, Fats and Oils - Production, Consumption and Stocks, and Ethanol: 2001-2004: EIA, Petroleum Supply Annual, Tables 2 and 16. Calculated as ten percent of oxygenated finished motor gasoline field production (Table 2) plus fuel ethanol refinery input (Table 16). 2005: EIA Petroleum Supply Annual 2005, Tables 1 and 15. Calculated as motor gasoline blending components adustments (Table 1), plus finished motor gasoline adjustments (Table 1), plus fuel ethanol refinery and blender net inputs (Table 15). 2006: EIA Petroleum Supply Monthly, monthly reports, Tables 1 and 27. Calculated as motor gasoline blending components adjustments (Table 1), plus finished motor gasoline adjustments (Table 1 adjustments (Table 1), plus finished motor gasoline adjustments (Table 1), plus finished motor gasoline adjustments (Table 1), plus fuel ethanol refinery and blender net inputs (Table 27). Small amounts of ethanol consumption are distributed to the commercial and industrial sectors according to those sector's shares of U.S. motor gasoline supplied. Electric Power: Energy Information Administration, Form EIA-920, "Combined Heat and Power Plant Report.

Sources: Analysis conducted by Energy Information Administration, Office of Coal, Nuclear, Electric, and Alternate Fuels and Specific sources described as follows. Residential: Energy Information Administration, Form EIA-457A/G, "Residential Energy Consumption Survey;"Oregon Institute of Technology, Geo-Heat Center and Energy Information Administration, Form EIA-63-A, "Annual Solar Thermal Collector Manufacturers Survey" and Form EIA-63B, "Annual Photovoltaic Module/Cell Manufacturers Survey." Commercial: Energy Information Administration, Form EIA-867, "Annual Nonutility Power Producer Report," Form EIA-860B, "Annual Electric Generator Report - Nonutility," Form EIA-906, "Power Plant Report," Form EIA-920, "Combined Heat and Power Plant Report," and Oregon Institute of Technology, Geo-Heat Center.Industrial: Energy Information Administration, Form EIA-860, "Manufacturing Energy Consumption Survey," Form EIA-867, "Annual Nonutility Power Producer Report," Form EIA-860B, "Annual Electric Generator Report - Nonutility," Form EIA-906, "Power Plant Report", and Form EIA-902, "Combined Heat and Power Plant Report," Oregon Institute of Technology, Geo-Heat Center; Government Advisory Associates, Resource Recovery Yearbook and Methane Recovery Yearbook; U.S. Environmental Protection Agency, Landfill Methane Outreach Program estimates; and losses and coproducts from the production of biodiesel and ethanol calculated as the difference between energy in feedstocks and production. Biofuels for Transportation: Biodiesel: 2001-2005: U.S. Department of Agriculture, Commodity Credit Corporation, Bioenergy Program estimates of production assigned to consumption and 2006 and forward: U.S. Department of Commerce, Bureau of Census, Current Industrial Reports, Fats and Oils - Production, Consumption and Stocks, and Ethanol: 1989: EIA, Estimates of U.S. Biofuels Consumption 1990, Table 10, 1990-1992; EIA, Estimates of Ú.S. Biomass Energy Consumption 1992, Table D2, 1993-2004; EIA, Petroleum Supply Monthly, Tables 2 and 16. Calculated as ten percent of oxygenated finished motor gasoline field production (Table 2) plus fuel ethanol refinery input (Table 16).2005: EIA Petroleum Supply Annual 2005, Tables 1 and 15. Calculated as motor gasoline blending components adustments (Table 1), plus finished motor gasoline adjustments (Table 1), plus fuel ethanol refinery and blender net inputs (Table 15).2006: EIA Petroleum Supply Monthly, monthly reports, Tables 1 and 27. Calculated as motor gaoline blending components adjustments (Table 1), plus finished motor gaosline adjustments (Table 1), plus fuel ethanol refinery and blender net inputs (Table 27). Small amounts of ethanol consumption are distributed to the commercial and industrial sectors according to those sector's shares of U.S. motor gasoline supplied. Electric Power: Energy Information Administration, Form EIA-759, "Monthly Power Plant Report, "Form EIA-867, "Annual Nonutility Power Producer Report, "Form EIA-860B," Annual Electric Generator Report - Nonutility," and Form EIA-906 "Monthly Power Plant Report,"

Table 1.6. Biofuels Overview, 2002-2006 (Trillion Btu)

Туре	2002	2003	2004	2005	2006

Production i	1	2	4	12	32	

- a Total corn and other biomass inputs to the production of fuel ethanol.
- b Losses and co-products from the production of fuel ethanol. Does not include natural gas, electricity, and other non-biomass energy used in the production of fuel ethanol.
- c Fuel ethanol production. d Fuel ethanol imports. There are no exports.
- e Fuel ethanol stock change. A negative number indicates a decrease in stocks and a positive number indicates an increase. If Fuel ethanol consumption equals fuel ethanol production, plus fuel ethanol net imports, minus fuel ethanol stock change.
- g Total soy bean oil and other biomass inputs to the production of biodiesel.
- h Losses and co-products from the production of biodiesel. Does not include
- natural gas, electricity, and other non-biomass energy used in the production of biodiesel.
- Production of biofuels for use as diesel fuel substitutes or additives. Biodiesel consumption equals biodiesel production. NA=Not available.
- *=Less than 0.5 trillion Btu.

Note: Totals may not equal sum of components due to independent rounding. Sources: (Note: For ethanol and biodiesel heat contents, see Table 10.) Ethanol Feedstock: Calculated as fuel ethanol production multiplied by the approximate heat content of the corn and other biomass inputs to the production of fuel ethanol. Ethanol Losses and Co-products: Calculated as ethanol feedstock minus fuel ethanol production. Ethanol Production: 2002 and forward: Energy Information Administration (EIA), Form EIA-819, "Monthly Oxygenate Report," and predescessor form. Ethanol Net Imports, Stocks and Stock Change: 2002-2005: EIA, Petroleum Supply Annual (PSA), annual reports. 2006: EIA, Petroleum Supply Monthly (PSM), monthly reports. Ethanol Consumption: 2002-2004: EIA, PSA, annual reports, Tables 2 and 16. Calculated as ten percent of oxygentated finished motor gasoline field production (Table 2), plus fuel ethanol refinery input (Table 16), 2005: EIA, PSA 2005, Tables 1 and 15. Calculated as motor gasoline blending components adjustments (Table 1), plus finished motor gasoline adjustments (Table 1), plus fuel ethanol refinery blender net inputs (Table 15). 2006: EIA, PSM, monthly reports, Tables 1 and 27. Calculated as motor gasoline blending components adjustments (Table 1), plus finished motor gasoline adjustments Production: 2001-2005 U.S. Department of Agriculture, Commodity Credit Corporation, Bioenergy Program records and 2006 and forward: U.S. Department of Commerce, Bureau of Census, Current Industrial Reports, Fats and Oils - Production, Consumption and Stocks, and analysis conducted by Energy Information Administration, Office of Coal, Nuclear, Electric and Alternate Fuels.

Nonrenewable Total	809,236	851,599	866,585	879,274	884,281

a Includes total capacity whose primary energy source is MSW.
 b Agriculture byproducts/crops, sludge waste and other biomass solids, liquids and gases. Does not include tires.
 c Black liquor, and wood/woodwaste solids and liquids.
 MSW=Municipal Solid Waste.
 Note: Data revisions are discussed in Highlights section. Revisions to biomass capacity removed tires from renewable waste energy.
 Totals may not add due to independent rounding.

a Includes landfill gas and MSW biogenic (Paper and paper board, wood, food, leather, textiles and yard trimmings.).
 b Agriculture byproducts/crops, sludge waste and other biomass solids, liquids and gases.
 c Black liquor, and wood/woodwaste solids and liquids.
 *=Less than 500 kilowatthours

PV=Photovoltaic. MSW=Municipal Solid Waste.

Note: Revisions to biomass removed MSW non-biogenic and tires from renewable waste energy. The electric power sector comprises electricity-only and combined-heat-power (CHP) plants within North American Classification System (NAICS) 22 category whose primary business is to sell electricity, or electricity and heat, to the public. Dash indicates the state has no data to report for that energy source. Totals may not equal sum of components due to independent rounding.

a Includes landfill gas and MSW biogenic (Paper and paper board, wood, food, leather, textiles and yard trimmings.). b Agriculture byproducts/crops, sludge waste and other biomass solids, liquids and gases. c Black liquor, and wood/woodwaste solids and liquids. *=Less than 500 kilowatthours
PV=Photovoltaic.

MSW=Municipal Solid Waste.

Note: Revisions to biomass removed MSW non-biogenic and tires from renewable waste energy. Dash indicates the state has no data to report for that energy source. Totals may not equal sum of components due to independent rounding.

Source: Energy Information Administration, Form EIA-906,"Power Plant Report," and Form EIA-920, "Combined Heat and Power Plant Report."

a Includes landfill gas and MSW biogenic (Paper and paper board, wood, food, leather, textiles and yard trimmings.).
 b Agriculture byproducts/crops, sludge waste and other biomass solids, liquids and gases.
 c Black liquor, and wood/woodwaste solids and liquids.
 *=Less than 500 kilowatthours

PV=Photovoltaic. MSW=Municipal Solid Waste.

Note: Revisions to biomass removed MSW non-biogenic and tires from renewable waste energy. The electric power sector comprises electricity-only and combined-heat-power (CHP) plants within North American Classification System (NAICS) 22 category whose primary business is to sell electricity, or electricity and heat, to the public. Dash indicates the state has no data to report for that energy source. Totals may not equal sum of components due to independent rounding.

a Includes landfill gas and MSW biogenic (Paper and paper board, wood, food, leather, textiles and yard trimmings.).
 b Agriculture byproducts/crops, sludge waste and other biomass solids, liquids and gases.
 c Black liquor, and wood/woodwaste solids and liquids.
 *=Less than 500 kilowatthours
 PV=Photovoltaic.

MSW=Municipal Solid Waste.

Note: Revisions to biomass removed MSW non-biogenic and tires from renewable waste energy. Dash indicates the state has no data to report for that energy source. Totals may not equal sum of components due to independent rounding.

^a Total capacity whose primary energy source is landfill gas or MSW.

Source: Energy Information Administration, Form EIA-860,"Annual Electric Generator Report."

b Agriculture byproducts/crops, sludge waste and other biomass solids, liquids and gases. c Black liquor, and wood/woodwaste solids and liquids.

PV=Photovoltaic. MSW=Municipal Solid Waste. *=Less than 500 kilowatts.

Note: Revisions to biomass capacity removed tires from renewable waste energy. The electric power sector comprises electricity-only and combined-heat-power (CHP) plants within North American Classification System (NAICS) 22 category whose primary business is to sell electricity, or electricity and heat, to the public. Dash indicates the state has no data to report for that energy source. Totals may not equal sum of components due to independent rounding.

PV=Photovoltaic. MSW=Municipal Solid Waste. *=Less than 500 kilowatts.

Note: Revisions to biomass capacity removed tires from renewable waste energy. The electric power sector comprises electricity-only and combined-heat-power (CHP) plants within North American Classification System (NAICS) 22 category whose primary business is to sell electricity, or electricity and heat, to the public. Dash indicates the state has no data to report for that energy source. Totals may not equal sum of components due to independent rounding.
