Annual Energy Outlook 2017

AEO2017 Rollout Presentation
Johns Hopkins School of Advanced International Studies
January 5, 2017 | Washington, D.C.

By
Adam Sieminski, Administrator
Key takeaways from AEO2017

• With strong domestic production and relatively flat demand, the United States becomes a net energy exporter over the projection period in most cases

• U.S. crude oil production rebounds from recent lows, driven by continued development of tight oil resources; with consumption flat to down compared to recent history, net crude oil and petroleum product imports as a percentage of U.S. product supplied decline across most cases

• Across most cases, natural gas production increases despite relatively low and stable natural gas prices, supporting higher levels of domestic consumption and natural gas exports; projections are sensitive to resource and technology assumptions

• With modest demand growth, the primary driver for new electricity generation capacity in the Reference case is the retirement of older, less efficient fossil fuel units, largely spurred by the Clean Power Plan (CPP), and the near-term availability of renewable tax credits; even if the CPP is not implemented, low natural gas prices and the tax credits result in natural gas and renewables as the primary sources of new generation capacity; the future generation mix is sensitive to the price of natural gas and the growth in electricity demand
Key takeaways from AEO2017 (continued)

• Transportation energy consumption peaks in 2018 in the Reference case because rising fuel efficiency outweighs increases in total travel and freight movements throughout the projection period.

• Despite growth in the number of households and the amount of commercial floorspace, improved equipment and efficiency standards contribute to residential and commercial consumption remaining relatively flat or declining slightly from 2016 to 2040 in the Reference case.

• With economic growth and relatively low energy prices, energy consumption in EIA's three industrial sub-sectors (energy-intensive manufacturing, non-energy-intensive manufacturing, and nonmanufacturing) increases during the projection period across all cases; energy intensity declines in the Reference case and most side cases as a result of technological improvements.
Overview
AEO2017 includes side cases with different assumptions of macroeconomic growth, world oil prices, technological progress, and energy policies

- Oil prices are primarily driven by global market balances that are mainly influenced by factors external to the NEMS model; in the High Oil Price case, the price of Brent crude in 2016 dollars reaches $226 per barrel (b) by 2040, compared to $109/b in the Reference case and $43/b in the Low Oil Price case

- In the High Oil and Gas Resource and Technology case, lower costs and higher resource availability than in the Reference case allow for higher production at lower prices; in the Low Oil and Gas Resource and Technology case, more pessimistic assumptions about resources and costs are applied

- The effects of economic assumptions on energy consumption are addressed in the High and Low Economic Growth cases, which assume compound annual growth rates for U.S. gross domestic product of 2.6% and 1.6%, respectively, from 2016–40, compared with 2.2% annual growth in the Reference case

- A case assuming that the Clean Power Plan (CPP) is not implemented can be compared to the Reference case to show how that policy could affect energy markets and emissions

- Although the graphics in this presentation focus on projections through 2040, this AEO is the first projection to include model results through 2050, which are available on the AEO page of the EIA website; EIA welcomes feedback on the assumptions and results from the period 2040–50
Energy consumption varies minimally across all AEO cases, bounded by the High and Low Economic Growth cases.

Total energy consumption
quadrillion British thermal units

Energy related carbon dioxide emissions decline in most AEO cases, with the highest emissions projected in the No Clean Power Plan case.
Reference case energy-related carbon dioxide emissions fall, but at a slower rate than in the recent past

U.S. energy-related carbon dioxide emissions (Reference case)
billion metric tons of carbon dioxide

Source: EIA, Annual Energy Outlook 2017
Although population and economic output per capita are assumed to continue rising, energy intensity and carbon intensity are projected to continue falling in the Reference case.

Transportation energy use declines between 2018 and 2034 in the Reference case, driven by improvements in fuel economy.
Natural gas
U.S. dry natural gas production is the result of continued development of shale gas and tight oil plays, alternative assumptions cause significant differences.
Increasing demand from industrial and electric power markets drive rising domestic consumption of natural gas in the Reference case.

January 5, 2017
Increased natural gas trade is dominated by liquefied natural gas exports in the Reference case.
U.S. LNG export levels vary across cases and reflect both the level of global demand, as well as by the difference between domestic and global natural gas prices.
